I'm working on a partition-based table, and I don't quite understand what a shard key is in this context. I have partitions on the column named Part_Name, so what's the difference between my shard key and my partition key? Is the shard key only a single column or does it also include all other columns? I understand the term Partition key as the column that is used for querying a table. I think I understand the term shard key as a row. So in the above example, what's the difference between Part_Name and the shard key? A: Shard key is the column that define the unique partition within the database. Partition key is just a way to organize the data in the different partitions. You can have a shard key and multiple partition key, and the shard key is not necessarily unique. If the data is still in one single row, you will always have only one partition per shard key. If the data is in multiple rows, you will have multiple partitions per shard key. That said, partition is a way to organize data, not a data organization principle. It is quite similar to the example with the words "group" or "color". You group something in a group (color or partition) but you can have many groups (color or partition). You can always group data in as many ways as you want. 1. Field of the Invention This invention relates to a process for producing (meth)acrylic acid anhydride. More specifically, it relates to a process for producing (meth)acrylic acid anhydride from (meth)acrylic acid, which is produced by oxidation of (meth)acrolein. 2. Description of the Prior Art The (meth)acrylic acid anhydride of this invention is useful as a starting material for the production of N-substituted (meth)acrylamide derivatives, as a raw material for esterification reaction or polyester production, as an intermediate for the synthesis of various polymers, as an antifreeze or freezing stabilizer and so forth. It is known that the (meth)acrylic acid an 82157476af
