Observer variability in choriocapillaris OCT angiography measurements. To quantify interobserver variability in choriocapillaris OCT angiography (OCTA) measurements. Eighteen eyes of 18 healthy adults were imaged with spectral domain OCTA (Optovue, Inc, Fremont, CA) and subsequently reviewed and graded by 4 examiners. Choriocapillaris vessel density, flow density, and area were measured using a customized image analysis program. The number of vessel segments per second at each point on the scan and the area under the vascular tree of the inner retina were also calculated. Interobserver variability was tested using the intra-class correlation coefficient (ICC). Interobserver ICC varied from 0.668 for choriocapillaris area to 0.923 for flow density, 0.894 for number of vessel segments, and 0.922 for flow area. The number of vessel segments was the only OCTA variable with an ICC>0.75 across all examiners. With the use of flow area maps, the measurement variability increased for all parameters. Choriocapillaris area and flow density are the most reproducible measurements using choriocapillaris OCTA. The higher reproducibility of flow density suggests that either of these measurements could be used to compare over time, whereas the more consistent measurements of flow area may be better suited for other types of studies f678ea9f9e
