The current study investigates the three-dimensional (3-D) flow field in the healthy human thoracic aorta using an incompressible single-stroke model. Over the last two decades, multidirectional flow analyses of the aortic arch and its branches have been reported in healthy subjects by many groups. In this work, a baseline pressure-velocity-wall shear stress (WSS) configuration, a previously studied model of the thoracic aortic arch in a healthy human subject, is employed. The model has been extended to include the inflow from the brachiocephalic artery. The 3-D flow field for the aortic arch and its branches is analyzed at steady state by solving the incompressible Navier-Stokes equations and using a model of the human aorta. The pressure and velocity boundary conditions are obtained by solving the Navier-Stokes equations for a brachiocephalic inflow and forcing the aortic arch and its branches to assume the unstressed configuration. This is accomplished by using the residual stress fields of the aortic wall in the unstressed configuration to maintain a vanishing displacement field in the aortic arch and its branches. The aortic wall is assumed to be isotropic and homogeneous. Furthermore, the wall thickness is considered to be a function of the distance from the arch so as to satisfy the small deformation assumption. The maximum number of available degrees of freedom in the aortic arch is evaluated at three different stroke lengths. For the unstressed configuration of the aorta and its branches, the relative errors in the computed
